# **Life Bounding for Durability Duty Cycles**

***Mark A. Przeslawski  
nCode International Inc.***

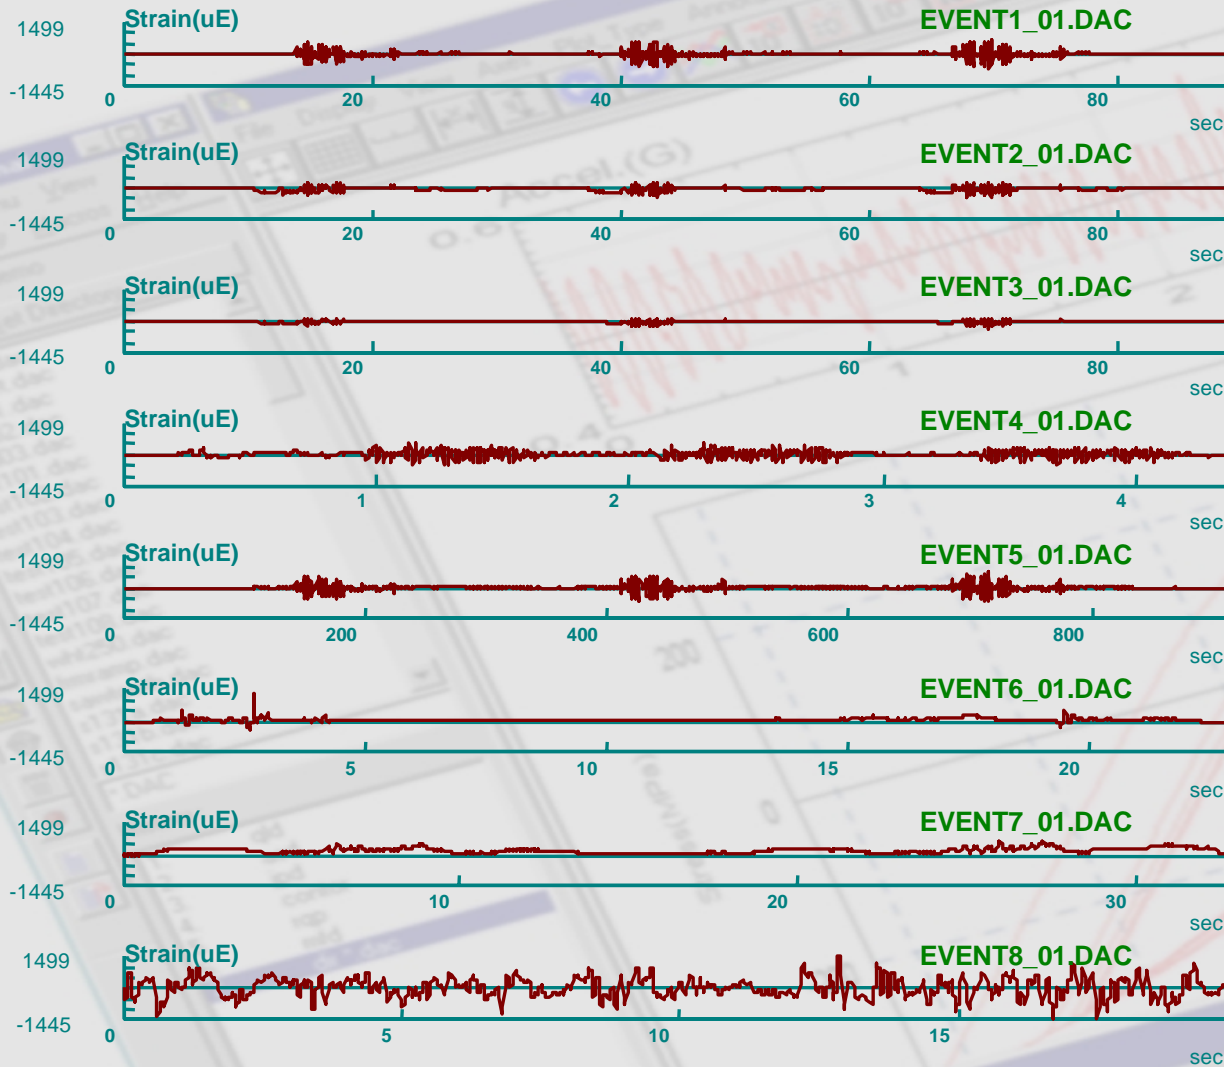

- **Evaluate durability over a complete “life”**
  - Proving Ground durability schedule is made up of many repeats of various events
  - Vehicle may run 20,000 durability miles to simulate 100,000 real-world miles
- **Instrumented vehicle collects data over all the proving ground events**
  - Blocks, potholes, ABS stop, bumps, etc.
  - Data is then used for fatigue analysis

# Fatigue Analysis Challenge

- **Due to time constraints, only 1 pass of each surface event may be collected**
  - Ideal to have more for statistical evaluation
- **Must take collected data and scale it by a multiplier**
  - Multiplier is the number of repeats for each surface event that is run for an entire durability schedule (or duty cycle)

# Sample Event Files

Max Y = 716.2  
Min Y = -651

Max Y = 202.8  
Min Y = -424.5

Max Y = 136  
Min Y = -311.8

Max Y = 575.8  
Min Y = -466.8

Max Y = 710.9  
Min Y = -641.2

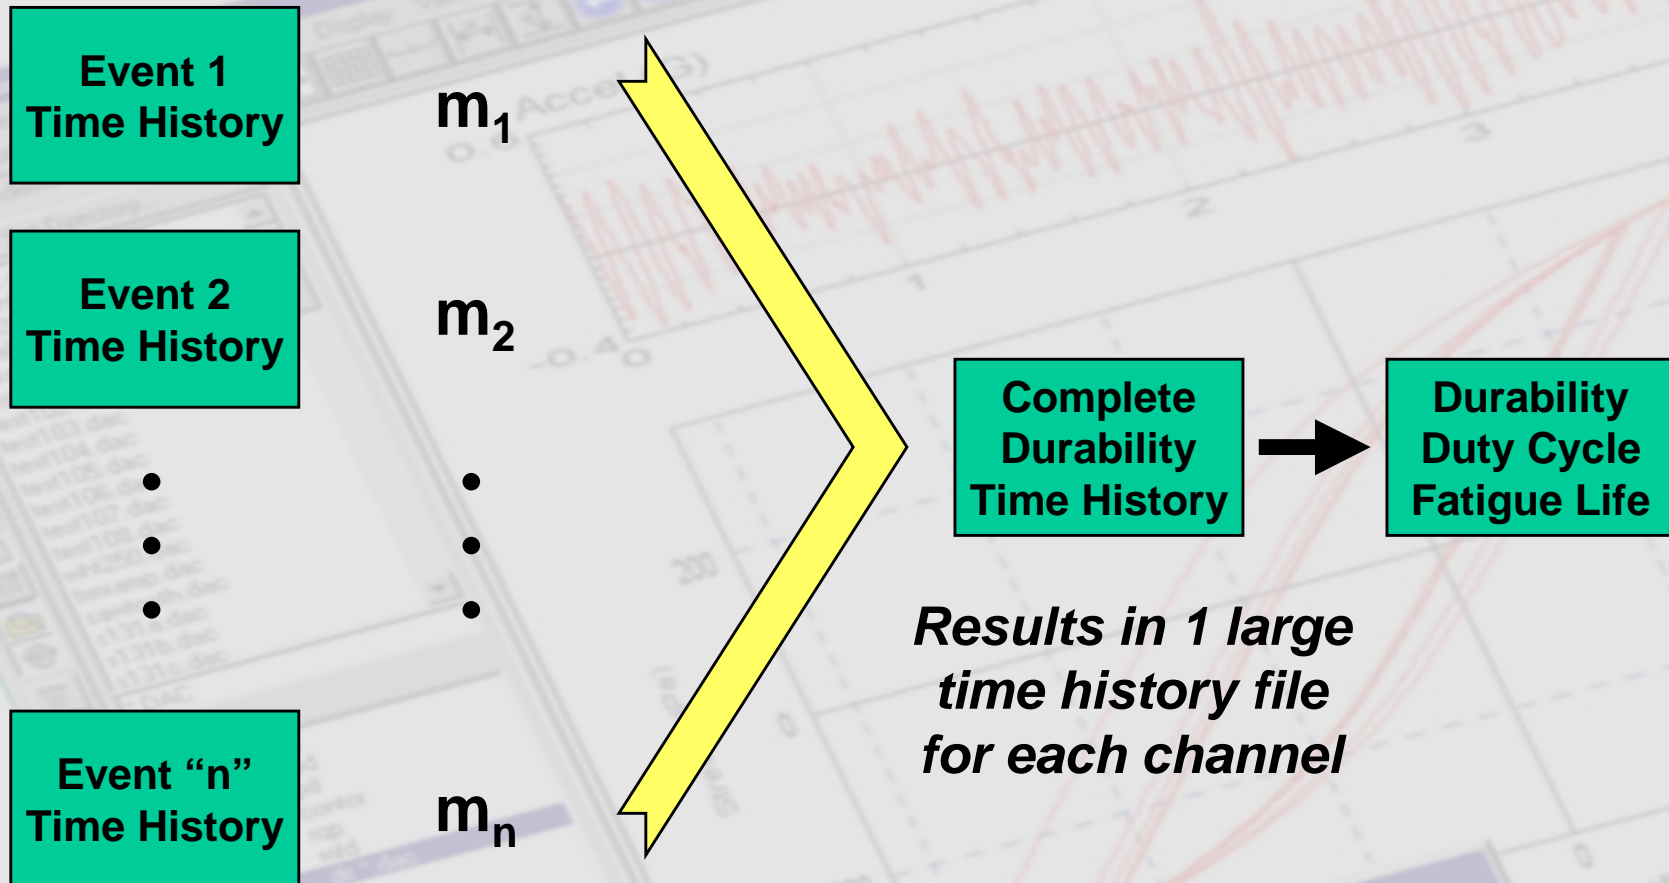

Max Y = 1301  
Min Y = -392.3

Max Y = 589.8  
Min Y = -0.344

Max Y = 1499  
Min Y = -1445

# Durability Fatigue Life Analysis

- Concatenate all events (each with their own multiplier)

# Drawbacks with Time History

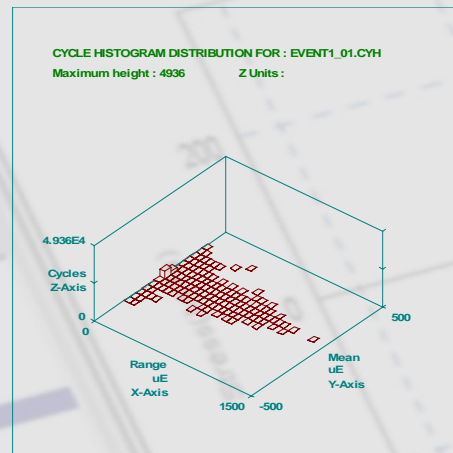

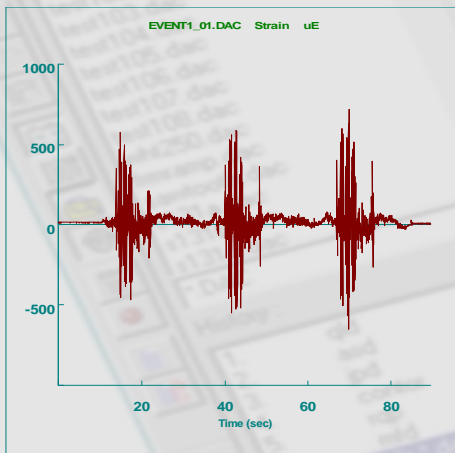

- **Large files for each channel**
- **Massive data storage needed**
- **Slower fatigue calculations**

# Life Bounding Analysis

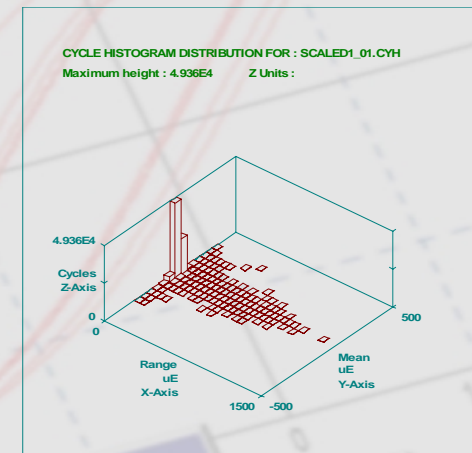

- **Create rainflow cycle matrix for each event**
  - **Must be same size!**
- **Multiply each event matrix by multiplier**
- **Add scaled matrices to form complete durability duty cycle matrix**
- **Perform fatigue calculations using rainflow matrices for each channel**

# Create Rainflow Matrices

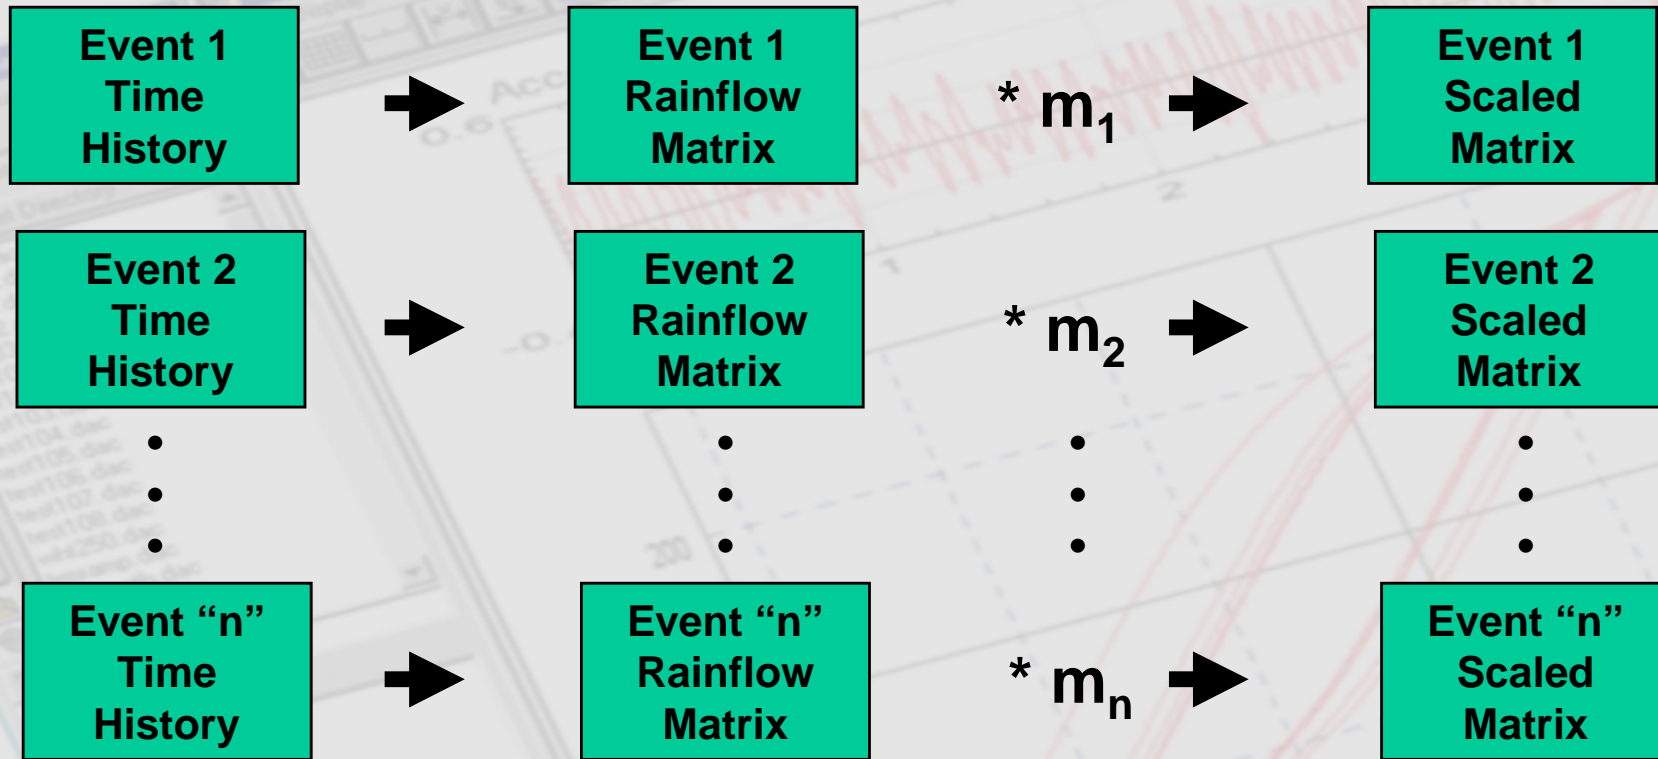

- For each event, create a rainflow cycle matrix and scale the matrix by the duty cycle multiplier

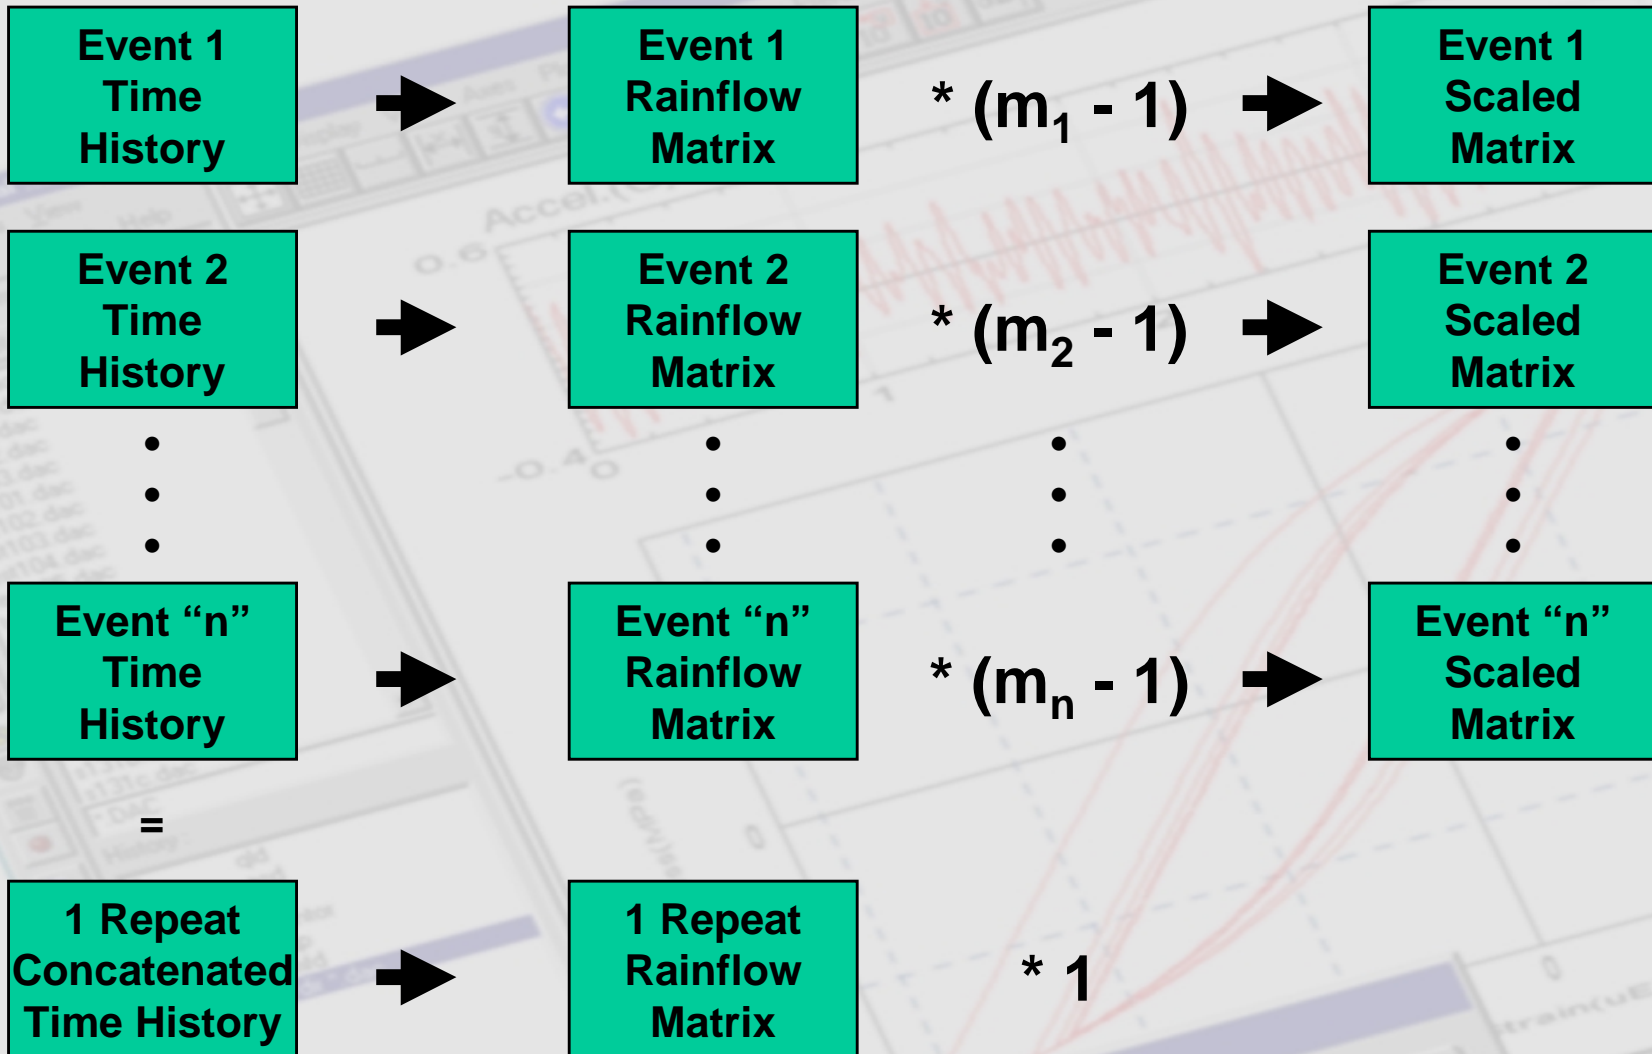

$* m_1$

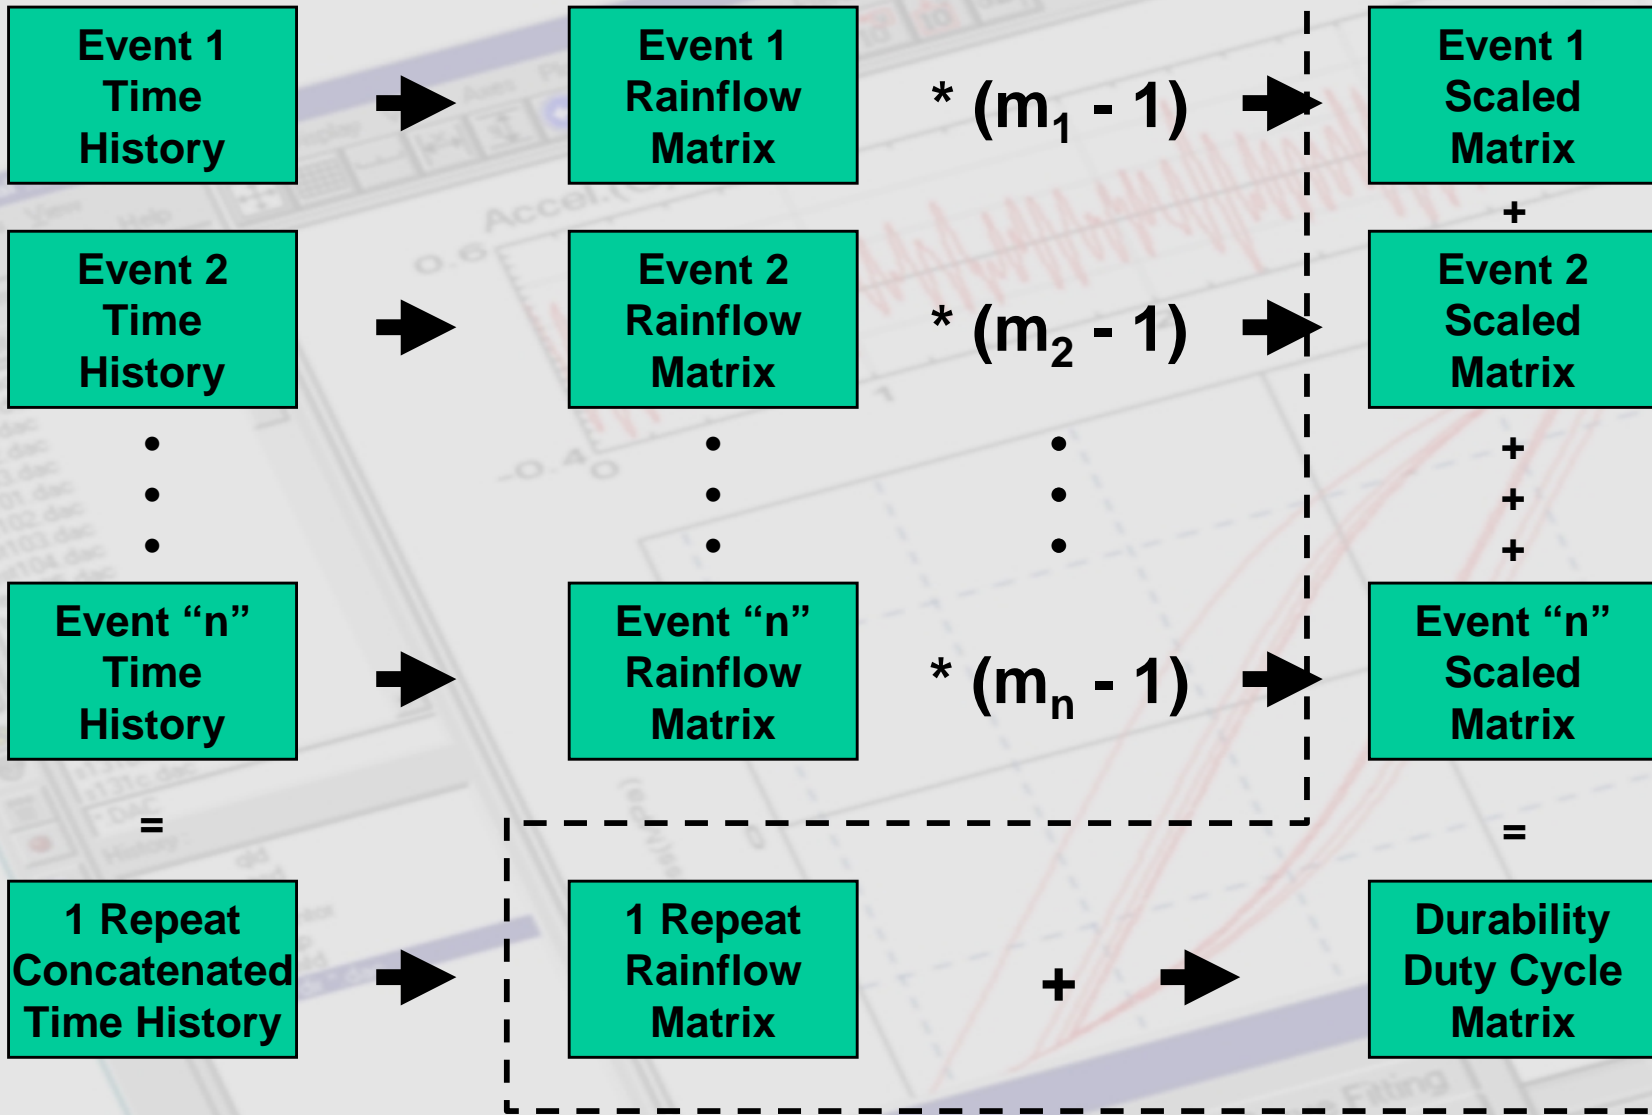

# Repeat for Every Event

# Account for Largest Cycle

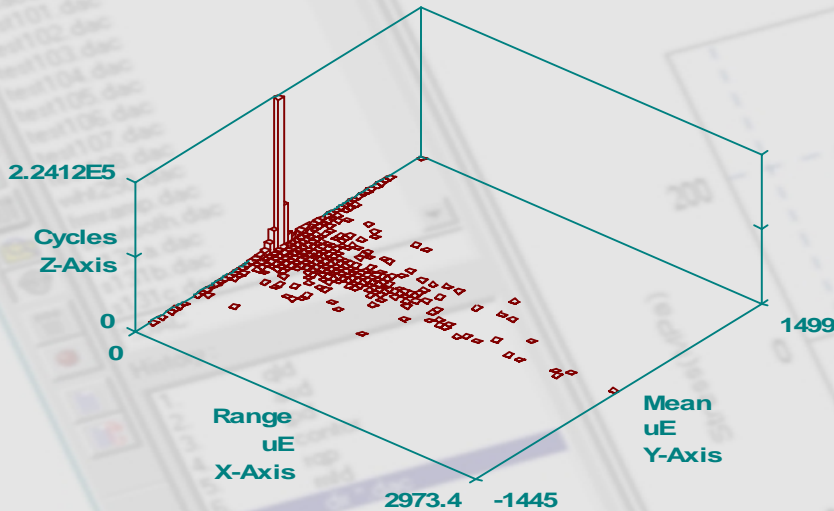

# Assemble Complete Matrix

- Compare 2 methods:

Concatenate time histories,  
then rainflow count

Rainflow count, multiply,  
then add matrices

- **Compare fatigue results:**

**Concatenate time histories,  
then calculate fatigue**

**Rainflow count, multiply, add  
matrices, then calculate fatigue**

CLF - Time Series Single Sh...	
Input Filename	CONCAT_01.DAC
Cycles Filename	None
Mean Stress Correction	S-W-T
Number of cycles counted	307319
% Low Cycle Damage	0 %
% Transition Damage	0 %
% High Cycle Damage	100 %
Estimated Life	701 Repeats

**Life = 701 repeats**

CLF - Histogram Single Sh...	
Input Filename	TOTEVT1_01.CYH
Output Filename	TOTEVT1_01.DHH
% Low Cycle Damage	0 %
% Transition Damage	0 %
% High Cycle Damage	100 %
Minimum Estimated Life	483 Repeats
Maximum Estimated Life	870 Repeats
Mean Estimated Life	676 Repeats

**Mean Life = 676 repeats**

**Min Life = 483**

**Max Life = 870**

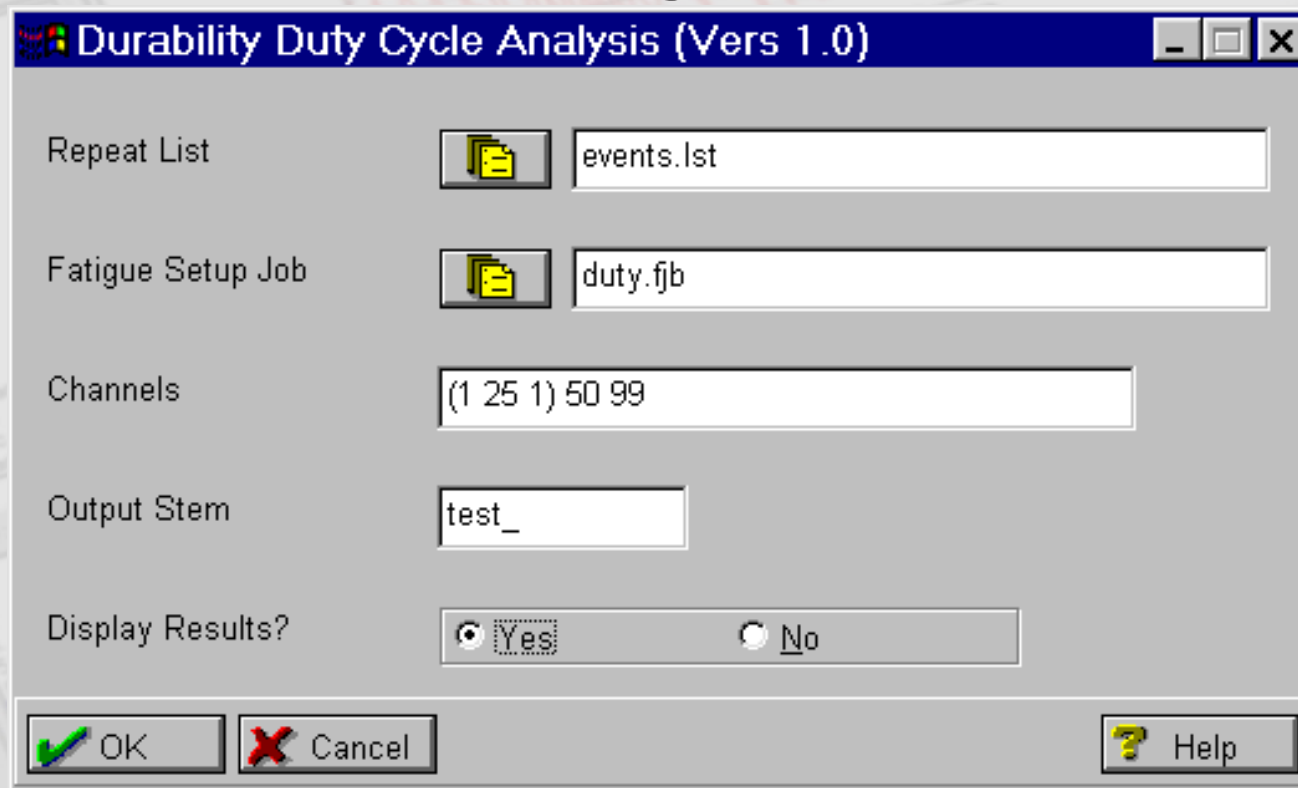

# Life Bounding Results

- Uncertainty in actual data value
- Should a bin value be taken as the minimum, mean, or maximum value in the bin?
- Life Bounding calculates results for all bins values
  - Time history results should fall within bounds

- **Must have all matrices same size**
  - Historical reference
- **Matrices are much smaller to store**
- **Not for multiaxial loading**
  - Other methods can be applied
- **Be careful of mean stress levels**
  - Data validation
- **Statistical extrapolation**
  - How many passes were collected
- **Automation**

- **Input multiplier file, channels**
  - Can calculate duty cycle matrix, % damage for events, overall damage, other

**Durability Duty Cycle Analysis (Vers 1.0)**
